

Very elementary number theory redone.

The natural numbers are 0, 1, 2 and so on; for further details, see Peano.

The positive integers are the natural numbers ≥ 1 , i.e. 1, 2, 3 and so on.

The multiples are the natural numbers ≥ 2 , i.e. 2, 3, 4 and so on. The product of two multiples is larger than each of those two; in formula

$$(\underline{\forall} x, y : x \geq 2, y \geq 2 : x \cdot y > x \wedge x \cdot y > y) \quad . \quad (1)$$

Multiples that are the product of two multiples are called composite; multiples that are not composite are called prime; in formula

$$\text{prime } m = m \geq 2 \wedge (\underline{\forall} x, y : x \geq 2, y \geq 2 : x \cdot y \neq m) \quad (2)$$

$$\text{comp } m = m \geq 2 \wedge (\underline{\exists} x, y : x \geq 2, y \geq 2 : x \cdot y = m) \quad (3)$$

In view of (1), (3) can be rewritten

$$\text{comp } m = (\underline{\exists} x, y : 2 \leq x < m, 2 \leq y < m : x \cdot y = m) \quad (3')$$

From (3') it is clear that it is decidable whether a specific m is composite.

Note that we have $\neg(\text{prime } 1) \wedge \neg(\text{comp } 1)$.

With PF -for Prime Factorization- defined by

$\text{PF } n = n \text{ is the product of (zero or more) multiples,}$
 $\text{all of which are prime (the empty product being defined as 1)}$

we can state

Theorem 0. $(\underline{\Lambda} n : n \geq 1 : \text{PF } n)$

Proof. We shall prove Theorem 0 by mathematical induction, i.e. we shall prove

$$(\underline{\Lambda} n : n \geq 1 : (\text{PF } n) \vee (\underline{\exists} i : 1 \leq i < n : \neg (\text{PF } i))) \quad (4)$$

Because $(\underline{\Lambda} n : n \geq 1 : n=1 \vee (\text{prime } n) \vee (\text{comp } n))$ and
 the product of one number equals that number, we deduce from the definition of PF

$$(\underline{\Lambda} n : n \geq 1 : (\text{comp } n) \vee (\text{PF } n)) \quad (5)$$

Furthermore we deduce from the definition of PF

$$(\underline{\Lambda} x, y : x \geq 1, y \geq 1 : \neg (\text{PF } x) \vee \neg (\text{PF } y) \vee \text{PF}(x, y))$$

from which we deduce with (3')

$$(\underline{\Lambda} n : n \geq 1 : \neg (\text{comp } n) \vee (\text{PF } n) \vee (\underline{\exists} i : 1 \leq i < n : \neg (\text{PF } i))) \quad (6)$$

From (5) and (6), relation (4) follows by the standard

inference rule. (End of Proof of Theorem 0.)

Theorem 1. ($\underline{\lambda} p: \text{prime } p : (\underline{\exists} q : q > p : \text{prime } q)$)

(This is Euclid's famous theorem that no prime is the largest one.)

Proof. Consider for arbitrary prime p the value Q defined by

$Q = 1 + \text{the product of all primes } \leq p$.

Theorem 0 allows us to conclude that Q is the product of a bag of primes, and, because $Q > 1$, that bag is not empty. By virtue of Q 's construction, such a bag contains no prime $\leq p$. Hence it contains at least one prime $> p$, hence at least one prime $> p$ exists.
(End of Proof of Theorem 1.)

With UPF -for Unique Prime Factorization- defined by

UPF $n =$ the bag of prime multiples whose product equals n is unique

we can formulate

Theorem 2. ($\underline{\lambda} p, x, y : p \geq 1, x \geq 1, y \geq 1 :$
 $\neg(\text{prime } p) \vee \neg(p | (x \cdot y)) \vee p | x \vee p | y \vee \neg(\text{UPF}(x, y))$)

(Here " $a|b$ " should be read as "a divides b".)

Proof. When the first two terms are false, $x.y$ is the product of a bag of primes containing p ; when the next two terms are false, $x.y$ is also the product of a bag of primes not containing p . Those two bags being different, we deduce $\neg(\text{UPF}(x.y))$.
 (End of Proof of Theorem 2.)

We are now ready to state and prove

Theorem 3. ($\underline{\forall} n: n \geq 1: \text{UPF}_n$)

Proof. Theorem 3 is proved by mathematical induction, i.e. by proving

$$(\underline{\forall} n: n \geq 1: (\text{UPF}_n) \vee (\underline{\exists} i: 1 \leq i < n: \neg(\text{UPF}_i))) \quad (7)$$

Inspired by our proof of Theorem 0, we observe that (7) follows from (8) and (9), given by

$$(\underline{\forall} n: n \geq 1: (\text{comp } n) \vee (\text{UPF}_n)) \quad (8)$$

$$(\underline{\forall} n: n \geq 1: \neg(\text{comp } n) \vee (\text{UPF}_n) \vee (\underline{\exists} i: 1 \leq i < n: \neg(\text{UPF}_i))) \quad (9)$$

Of these two, (8) follows immediately from (2), (3) and the definition of UPF. Assertion (9) requires, however, a more elaborate argument.

Consider a value of n , m say, such that the first and the last terms of (9) are false, i.e. such that

$$(\text{comp } m) \wedge (\underline{\forall i: 1 \leq i \leq m: \text{UPF}_i}) \quad (10)$$

holds. Because m is composite, it can be written as

$$m = p \cdot P = q \cdot Q \quad \text{with} \quad (11)$$

- 1) prime p
- 2) $p \leq q$
- 3) P standing for the product of a non-empty bag of primes all of which are $\geq p$
- 4) Q standing for the product of a bag of primes all of which are $\geq q$.

We obviously have $2 \leq P < m$, $1 \leq Q < m$, and $P \geq Q$.

The conclusion UPF_m , required to prove (9), can then be drawn from

$$p=q \vee (\text{comp } q) \quad (12)$$

as follows. When q is the smallest value in a bag of primes, $\text{comp } q$ is false and from (12) we deduce $p=q$. From (11) we deduce $P=Q$, and from (10) we deduce that P and Q stand for the same bag of primes. Since $p=q$, $p \cdot P$ and $q \cdot Q$ then also stand for the same bag of primes,

and UPF m has been established.

Establishing (12) is now our only remaining obligation. It is trivial in the case $p=q$. In the case $p < q$ we consider the value M defined by

$$M = (q-p).Q$$

Because $1 \leq M < m$, we conclude from (10) UPF M. Because $M = q.Q - p.Q = p.P - p.Q = p.(P-Q)$, we conclude $p \mid M$. Since prime p, we now conclude from Theorem 2

$$p \mid (q-p) \vee p \mid Q \quad (13)$$

Since $1 \leq Q < m$, we conclude from (10) UPF Q, i.e. all the primes in the unique bag of primes whose product equals Q are $\geq q$, hence $> p$. The bag being unique, we conclude $\neg(p \mid Q)$. In combination with (13) we conclude $p \mid (q-p)$; since we were considering the case $p < q$, we can conclude that q is composite. Having thus established relation (12), we have fulfilled our last proof obligation. (End of Proof of Theorem 3.)

Corollary of Theorems 2 and 3.

$$\begin{array}{c} (\text{A } p, x, y : p \geq 1, x \geq 1, y \geq 1 : \\ \neg(\text{prime } p) \vee \neg(p \mid (x.y)) \vee p \mid x \vee p \mid y) . \\ * \quad * \quad * \end{array}$$

The above was written in reaction to the presentation in [1] of essentially the same proof of Theorem 3. I found that presentation contorted and notationally clumsy. They write (for (11))

$$m = p_1 p_2 \cdots p_r = q_1 q_2 \cdots q_s$$

Note the dots and the need to introduce the subscripts r and s . A little later, after having excluded $p_1 = q_1$: "Suppose $p_1 < q_1$. (If $q_1 < p_1$ we simply interchange the letters p and q in what follows (sic).)" A third of a page later they conclude that "the prime decomposition of m' must be unique, aside from the order of the factors". Theorem 2 isn't mentioned and when needed in the proof of Theorem 3 they borrow the result from a corollary of Theorem 3! (Here their argument is almost cyclic.) And it is full of reductions ad absurdum.
