

A conversion routine revisited

In the following, $c(k: 1 \leq k)$ is a sequence of integers satisfying

$$(0) \quad c_k \geq 2 \quad \text{for all } k \geq 1,$$

but, for the time being, only $c_k \neq 0$ is relevant: it allows us to define $w(k: 0 \leq k)$ by

$$(1) \quad w_0 = 1$$

$$(2) \quad w_{k+1} = c_k * w_k \quad \text{for all } k \geq 1.$$

We now consider the following program defining the sequence $d(k: 1 \leq k)$ in terms of the real number R

```

n, f := 0, R {P0}
; do true → n := n + 1 {P1}
      ; d_n, f := INTFRA.(f * c_n) {P0}
      od
    
```

where, for the time being, our only knowledge about the pair-valued function INTFRA of a real argument is

$$(3) \quad x, y = \text{INTFRA}.z \Rightarrow x + y = z$$

The above suffices to demonstrate the invariance of P0: $R = (\sum_{k: 0 < k \wedge k \leq n} d_k * w_k) + f * w_n$ (leaving the fact that n is natural understood).

In order to verify that the initialization establishes P_0 we observe

$$\begin{aligned}
 & \text{wp. } "n, f := 0, R". P_0 \\
 = & \{ \text{axiom of assignment, definition of } P_0 \} \\
 & R = (\sum_{k: 0 < k \wedge k \leq 0} d_k * w_k) + R * w_0 \\
 = & \{ \text{definition of empty sum}; (1) \} \\
 & R = 0 + R * 1 \\
 = & \{ \text{arithmetic} \} \\
 & \text{true} .
 \end{aligned}$$

In order to verify the invariance of P_0 we observe - after introducing the abbreviation S :

$$S = d_n, f := \text{INTFRA}.(f * c_n) -$$

for $n \geq 1$

$$\begin{aligned}
 & \text{wp. } S. P_0 \\
 = & \{ \text{definition of } P_0 \} \\
 & \text{wp. } S. (R = (\sum_{k: 0 < k \wedge k \leq n} d_k * w_k) + f * w_n) \\
 = & \{ \text{splitting the range, as } n \geq 1 \} \\
 & \text{wp. } S. (R = (\sum_{k: 0 < k \wedge k \leq n-1} d_k * w_k) + \\
 & \quad (d_n + f) * w_n) \\
 = & \{ \text{axiom of assignment, definition of } S, (3) \} \\
 & (\sum_{k: 0 < k \wedge k \leq n-1} d_k * w_k) + f * c_n * w_n \\
 = & \{ (2) \text{ with } k := n \} \\
 & (\sum_{k: 0 < k \wedge k \leq n-1} d_k * w_k) + f * w_{n-1} \\
 = & \{ \text{definition of } P_0 \text{ and of substitution} \} \\
 & (n := n-1). P_0 \\
 = & \{ \text{our nomenclature} \} \\
 & P_1
 \end{aligned}$$

Since [wp. " $n := n+1$ ". $P_1 \equiv P_0$], the invariance of P_0 has now been established.

* * *

Our next target is

$$(4) \quad R = (\sum k : 0 < k : d_k * w_k) \quad ,$$

a relation which follows from P_0 if

$$(5) \quad \lim_{k \rightarrow \infty} f * w_k = 0 \quad .$$

In view of (0) -which now becomes relevant- and (2), $\lim_{k \rightarrow \infty} w_k = 0$, so (5) follows if f is bounded.

A look at the program tells us that boundedness of f depends on the function INTFRA, about which, up till now, only (3) has been given. For given z , the relation $x + y = z$ of (3)'s consequent can be satisfied in many ways: the one extreme, viz. $x=0 \wedge y=z$, leads to unbounded f , the other extreme, viz. $x=z \wedge y=0$ leads, instead of to the general (4), to $R = d_i * w_i$, which is not interesting. So we choose something in between.

The left element of INTFRA.z is constrained by

$$(6) \quad x, y = \text{INTFRA}.z \Rightarrow x \text{ is integer} \quad ,$$

which allows us to restrict y to a unit interval. For

the constraint on y we consider the following two alternatives:

$$(i) \quad x, y = \text{INTFRA}.z \Rightarrow 0 \leq y \wedge y < 1 \quad \text{and}$$

$$(ii) \quad x, y = \text{INTFRA}.z \Rightarrow 0 < y \wedge y \leq 1$$

We now restrict our investigation of these alternatives to $0 < R \wedge R < 1$; in the following it becomes relevant that c is a sequence of integers.

Alternative (i) leads to the invariance of

$$0 \leq f \wedge f < 1 \quad ;$$

alternative (ii) leads to the invariance of

$$0 < f \wedge f \leq 1 \quad .$$

In both cases we have for all k

$$0 \leq d_k \wedge d_k < c_k \quad .$$

The minimum value 0 and the maximum value c_{k-1} can in both cases occur for d_k .

For a given sequence c , we call an R -value sensitive if its corresponding sequence d depends on whether (i) or (ii) has been chosen, otherwise we call it insensitive. We shall see below that for any sequence c , values of both types exist.

Because of $0 < R \wedge R < 1$, the initialization of the program establishes

$$(7) \quad 0 < f \wedge f < 1 .$$

If with one of the alternatives for INTFRA, $f * c_n$ is never integer, (7) is an invariant and the computation is indistinguishable from the one with the same R but the other alternative for INTFRA: R is insensitive.
(E.g. $R = 1/2$ for $c_k = 3$.)

We now investigate the case in which, sooner or later, the repeatable statement falsifies (7). That occurs when, with f satisfying (7), $f * c_n$ is integer; let then

$$f * c_n, n = q, N$$

Because f satisfies (7), q satisfies

$$1 \leq q \wedge q < c_N .$$

The rest of the computation depends on which alternative has been chosen for INTFRA. With (i), the assignment is effectively

$$d_N, f := q, 0 ,$$

and, $f=0$ being stable with (i), the program defines

$$(\exists k: N < k: d_k = 0) ,$$

i.e. sequence d ends with $d_N > 0$, followed by "the minimum tail".

With (ii), the assignment is effectively

$$d_N, f := q-1, 1 ,$$

and, $f=1$ being stable with (ii), the program defines

$$(\underline{\forall} k: N < k: d_k = c_{k-1}) ,$$

i.e. sequence d ends with $d_N < c_{N-1}$, followed by "the maximum tail".

We conclude that an R giving rise to an integer $f * c_n$ is sensitive.

Remark With, for some positive N , $R = w_N$, R is sensitive. In view of (4), the above analysis tells us

$$(8) \quad w_N = (\sum_{k: N < k} (c_{k-1}) * w_k) .$$

(End of Remark.)

If R and d satisfy (4), we say that " d is a representation of R ", and in that terminology we just found that insensitive values have at least 1 representation and sensitive values have at least 2 representations. Under the constraint

$$(\underline{\forall} k: 0 < k: 0 \leq d_k \wedge d_k < c_k)$$

values don't have more representations. The argument relies primarily on the monotonicity of addition.

We ask ourselves under what circumstances two different sequences can represent the same value. Let X be the common prefix of the two sequences, in the one followed by "p tail" and in the other by "q tail", with $p < q$.

We now consider the following sequences and values

$X \ p \ \text{tail}_0$	R_0
$X \ p \ \text{maximum tail}$	R_1
$X \ p+1 \ \text{minimum tail}$	R_2
$X \ q \ \text{minimum tail}$	R_3
$X \ q \ \text{tail}_1$	R_4

Because in $\text{tail}_0 \ d_k < c_k$, $R_0 \leq R_1$ and $R_0 = R_1$
 $\Rightarrow \text{tail}_0 = \text{maximum tail}$. Because of (8), $R_1 = R_2$.

Because of $p < q$, $R_2 \leq R_3$; $R_2 = R_3 \Rightarrow p+1 = q$.

Because in $\text{tail}_1 \ 0 \leq d_k$, $R_3 \leq R_4$ and $R_3 = R_4$
 $\Rightarrow \text{minimum tail} = \text{tail}_1$. Because the sequence of R -values is ascending, $R_0 = R_4$ implies that they are all equal, hence

$$\text{tail}_0 = \text{maximum tail}$$

$$p+1 = q$$

$$\text{tail}_1 = \text{minimum tail},$$

and the two sequences representing the sensitive value are the ones generated according to (ii) and (i) respectively. Also: a sequence not ending in an extreme tail is insensitive.

In other words, the shape of the sequence - i.e. whether or not it has an extreme tail - determines whether the value represented by the sequence is sensitive or not.

Each sensitive R is rational. The fraction $\frac{1}{q}$ is sensitive provided, for some N , q divides the product of the first N c -values. Hence, each rational R is sensitive provided

$$(9) \quad (\exists q: 0 < q: (\exists N: q \text{ divides } (\prod_{k=0}^{N-1} c_k)))$$

Combining the two observations, we conclude

$$(9) \Rightarrow (R \text{ is sensitive}) \equiv (R \text{ is rational})$$

Condition (9) is clearly satisfied for $c_k = k+1$. Hence e , the basis of the natural logarithm, is irrational.
