

CS 378 – Big Data Programming

Lecture 16

Filtering Patterns

Review

- Assignment 7 – Filtering, Multiple Outputs
- Questions/issues:

Basic Filtering

- Some common basic filtering uses
 - `grep`
 - Random sample
 - Score records on some criterion, apply a threshold
 - Data cleansing

Distributed grep

- grep – Unix filtering utility
- Apply a regular expression to each input record
- Output records that match

Distributed grep

```
public static class GrepMapper
    extends Mapper<Object, Text, NullWritable, Text> {

    private String mapRegex = null;

    public void setup(Context context) throws IOException,
        InterruptedException {

        mapRegex = context.getConfiguration().get("mapregex");
    }

    public void map(Object key, Text value, Context context)
        throws IOException, InterruptedException {

        if (value.toString().matches(mapRegex)) {
            context.write(NullWritable.get(), value);
        }
    }
}
```

Simple Random Sampling

- Each input record has equal probability of selection
- Does the selection predicate need to examine the record?
 - If we want the equal probability condition, then no.
 - If we want a biased sample, we can consider the record
- Like basic filtering, consider output file size

Simple Random Sampling

```
private Random rands = new Random();
private Double percentage;

protected void setup(Context context) throws IOException,
    InterruptedException {
    // Retrieve the percentage that is passed in via the configuration
    //   like this: conf.set("filter_percentage", .5);
    //           for .5%
    String strPercentage = context.getConfiguration()
        .get("filter_percentage");
    percentage = Double.parseDouble(strPercentage) / 100.0;
}

public void map(Object key, Text value, Context context)
    throws IOException, InterruptedException {

    if (rands.nextDouble() < percentage) {
        context.write(NullWritable.get(), value);
    }
}
```

Bloom Filter - Review

- Bloom filter like the basic filter
- But selection predicate is:
 - Does record contain a value from a predefined set?
- This set may be too large to fit in memory
- Bloom filter is fixed size, but has false positives

Bloom Filter – Data Flow

Figure 3-2 from MapReduce Design Patterns

Bloom Filter - Review

- Bloom filter commonly used as map-only
 - Output files will have some false positives
 - Code examples in the book (pp. 53 – 57)
- We discussed how to combine Bloom filter with reduce-side join
 - Bloom filter represented user IDs with submit events
 - Applied in the mapper
 - Reduced the data sent to reduce
 - Reduce eliminated false positives (non-submit sessions)

Bloom Filter - Review

- Probabilistic data structure
 - Used to test whether something is in a predefined set
 - Can create “false positives”
 - Knows for sure that something is not a member of the set
 - Sometimes reports membership as true, when it is false
 - Never creates “false negatives”
 - Never reports “not a member” when it in fact it is a member
- Fixed size in memory
 - Train the filter using members of the set

Bloom Filter - Review

- Can add members to the set (further training)
 - Can't remove members
 - There is a technique that allows removal
- Parameters of the filter
 - Number of bits in a bit array
 - Number of independent hash functions
- These can be tuned to get a certain false positive rate

Top Ten (or Top N)

- We know that we want a specific number of outputs
 - Based on some evaluation/ranking criterion
- An obvious approach is to sort first
- But total sort is expensive for large data
 - In Hadoop, or in a database
- Output should be significantly smaller than the input
- How might we accomplish this without sort?

Top Ten (or Top N)

- Start with a comparison method
 - Given two records, which one is larger
- Each mapper finds the top ten from its data
- Each mapper sends its top ten to reduce
 - When?
- Reduce finds the final top ten
 - How many reducers?
- What key and value are sent to reduce?

Top Ten (or Top N)

```
class mapper:
    setup():
        initialize top ten sorted list

    map(key, record):
        insert record into top ten sorted list
        if length of array is greater-than 10 then
            truncate list to a length of 10

    cleanup():
        for record in top sorted ten list:
            emit null,record
```

Top Ten (or Top N)

```
class reducer:  
    setup():  
        initialize top ten sorted list  
  
    reduce(key, records):  
        sort records  
        truncate records to top 10  
        for record in records:  
            emit record
```

Top Ten (or Top N)

Top Ten (or Top N)

- Remember to copy records retained in `map()`
 - Why?
- Recall the key/value output by the mappers
 - Suppose we wanted the original key/value pair. How?
- Each mapper's Top N is output in `cleanup()`
 - How could we do Top N without using `cleanup()`?

Top Ten (or Top N)

- For top N, if N large, this pattern becomes inefficient
- Single reducer
- Data transferred to reduce
- Reduce input is sorted (expensive for large data)
- No parallel writes from reduce

Distinct

- Want only one record when duplicate records exist
- Map:
 - Extract the data of interest (if not the entire record)
 - Output this data as the key
 - Make the value output by `map()` `NullWritable`
- Reduce:
 - Simply write out each unique key (the data of interest)
 - Can use a large number of reducers

Distinct

- Can we use a combiner?
- If duplicates are rare, combiner doesn't help much
- If duplicates are common, or co-located, a combiner can greatly reduce the data transferred
- Suppose we want all the data in the record, and
 - The compare method is complex
 - Can we approach this problem differently?
