Parser Evaluation

View a parse as a set of labeled *brackets* / constituents

S(0,3) NP(0,1)PRP(0,1) (but standard evaluation does not count POS tags)

VP(1,3), VBD(1,2), NP(2,3), PRP(2,3)

Parser Evaluation

Parser Evaluation

- Standard dataset for English: Penn Treebank (Marcus et al., 1993)
- "Vanilla" PCFG: ~71 F1
- Best PCFGs for English: ~90 F1
- Other languages: results vary widely depending on annotation + complexity of the grammar

Results

State-of-the-art discriminative models (using unlabeled data): 95 F1

Refining Generative Grammars

PCFG Independence Assumptions

- [They]_{NP} received [the package of books]_{NP}

Language is not context-free: NPs in different contexts rewrite differently

Vertical Markovization

Annotating Trees

binarization

First apply vertical Markovization, then do another transformation during

- Can do some other specialized tag splits: e.g., sentential prepositions behave differently from other prepositions
- \sim 70 F1 => 86.3 F1 using these tricks

Tag Splits

Klein and Manning (2003)

Lexicalized Parsing, Dependency Parsing

- Annotate each grammar symbol with its "head word": most important word of that constituent
- Rules for identifying headwords (e.g., the last word of an NP before a preposition is typically the head)
- Collins and Charniak (late 90s): ~89 F1 with these

Lexicalized Parsers

Lexicalized Parsing

- Dependency syntax: syntactic structure is defined by these arcs Head (parent, governor) connected to dependent (child, modifier) Each word has exactly one parent except for the ROOT symbol, dependencies must form a directed acyclic graph

POS tags same as before, usually run a tagger first as preprocessing

Dependency Parsing

- Constituency tests:
 - Substitution by proform: the dog did so [ran to the house], he [the dog] ran to the house
 - Clefting (It was [to the house] that the dog ran...)
- Dependency: verb is the root of the clause, everything else follows from that
 - No notion of a VP!

Why are they defined this way?

Still a notion of hierarchy! Subtrees often align with constituents

Dependency Parsing

Can label dependencies according to syntactic function

(labeling separately with a classifier works pretty well)

Dependency Parsing

Major source of ambiguity is in the structure, so we focus on that more

Constituency: several rule productions need to change

Dependency vs. Constituency: PP Attachment

Dependency: one word (with) assigned a different parent

the children ate the cake with a spoon

- More predicate-argument focused view of syntax
- "What's the main verb of the sentence? What is its subject and object?" — easier to answer under dependency parsing

Dependency vs. Constituency: PP Attachment

Constituency: ternary rule NP -> NP CC NP

Dependency vs. Constituency: Coordination

Dependency: first item is the head

- single rule production as in constituency
- Can also choose and to be the head
- In both cases, headword doesn't really represent the phrase constituency representation makes more sense

Dependency vs. Constituency: Coordination

dogs in **houses and cats**

dogs in [houses and cats]

Coordination is decomposed across a few arcs as opposed to being a

Shift-Reduce Parsing (see notes)
