

Proving Invariants via Rewriting and Finite Search

ACL2 Seminar

August 18, 2004

Rob Sumners

robert.sumners@amd.com

[What are *Invariants*?]

- A *Term* is either a variable symbol, a quoted constant, or a function application

– Example:

```
(cons (binary-+ x (quote 1)) '(t . nil))
```

- Every *function* is either a function symbol or a `lambda` expression

- A *Predicate* is a term with a single variable symbol `n` and is interpreted in an `iff` context

– This is our non-standard definition of *Predicate*

- An *Invariant* is a predicate which we wish to prove is non-`nil` for all values of `n`.

– The variable `n` is intended to range over all values of natural-valued “time”

[Importance of Proving Invariants]

- Caution – over-generalized statement which I do not wish to debate:
 - Most properties of interest about concurrent, reactive systems can be effectively reduced to the proof of a sufficient invariant
- Invariants can be very difficult and tedious to prove for larger systems.
 - Many prime examples of this from our community and other formal methods communities
 - From ACL2 community: CLI stack work, Jun’s work, Pete’s work, JVM work, Sandip’s work, My work, etc.

[Example Invariant: Mutual Exclusion]

```
(encapsulate (((i *) => *))
  (local (defun i (n) n)))

(define-system mutual-exclusion

  (in-critical (n) nil
    (if (in-critical n-)
        (/= (i n) (critical-id n-))
        (= (status (i n) n-) :try)))

  (critical-id (n) nil
    (if (and (not (in-critical n-))
              (= (status (i n) n-) :try))
        (i n)
        (critical-id n-)))

  (status (p n) :idle
    (if (/= (i n) p) (status p n-)
        (case (status p n-)
            (:try (if (in-critical n-)
                      :try
                      :critical))
            (:critical :idle)
            (t :try))))))
```

[Specifying Mutual Exclusion]

- Property: No two distinct processes *a* and *b* can be in the `:critical` state at the same time
- Codified as the invariant `(ok n)`:

```
(encapsulate (((a) => *) ((b) => *))
  (local (defun a () 1))
  (local (defun b () 2))
  (defthm a-/-b (not (equal (a) (b))))
  (defthm a-non-nil (not (equal (a) nil)))
  (defthm b-non-nil (not (equal (b) nil))))

(defun ok (n)
  (not (and (= (status (a) n) :critical)
            (= (status (b) n) :critical))))
```

[Approaches - Theorem Proving]

- Define and prove an *inductive invariant* which implies the target invariant.

- For complex systems, the definition and/or proof of an inductive invariant is a non-trivial exercise

- For our mutual exclusion example:

```
(defun ii-ok-for1 (n i)
  (iff (= (status i n) :critical)
        (and (in-critical n)
              (= (critical-id n) i))))
```

```
(defun ii-ok (n)
  (and (ii-ok-for1 n (a)) (ii-ok-for1 n (b))))
```

```
(defthm ok-is-invariant
  (and (ii-ok 0)
        (implies (ii-ok n)
                  (and (ok n) (ii-ok (1+ n))))))
```

[Approaches - Model Checking]

- Explore an “effective” finite state graph of a system searching for failures
 - Specification is usually provided by a temporal logic formula: e.g. an invariant in CTL would be $AG(ok)$
 - System definition languages: Verilog HDL, VHDL, SMV, Mur ϕ , SPIN, Limited variants of C/C++, etc.
 - Model checkers are generally classified into explicit-state and implicit-state
 - Several algorithms exist to reduce large-state systems to effectively finite *abstract* state systems: symmetry reductions, partial order reductions, etc.
- Hybrid approaches: too many to enumerate, but most involve some form of abstraction.

[Our Approach - Phase 1]

- Assume the definition of a term rewrite function `rewrt` which takes a term as an input and produces the rewritten term

- For a predicate ϕ , denote ϕ' as the term:
`(rewrt '((lambda (n) , ϕ) (1+ n)))`

- Assume the following function definition:

```
(defun state-ps (trm)
  (cond ((or (atom trm) (quotep trm)) ())
        ((eq (first trm) 'if)
         (union-equal (state-ps (second trm))
                      (union-equal (state-ps (third trm))
                                    (state-ps (fourth trm))))))
        (t (and (state-predp trm) (list trm)))))
```

- Compute the least set of predicates Ψ s. t. :
(a) the target invariant predicate $\tau \in \Psi$, and
(b) for every $\phi \in \Psi$, `(state-ps ϕ')` $\subseteq \Psi$

[Our Approach - Phase 2]

- Given the finite predicate set Ψ , we first compute the finite set of input predicates Γ
 - For each predicate ϕ in Ψ and Γ , define a boolean variable $bv(\phi)$
 - The boolean variables for Ψ are state var.s and the variables for Γ are input var.s
- For each α in Ψ , we replace the predicate subterms ϕ in α' with $bv(\phi)$
 - This gives us a propositional next-state function for $bv(\alpha)$ in terms of the state and input boolean var.s
- Explore the graph of nodes defined by next-state functions starting from initial node
 - If no path is found to a node where $bv(\tau)$ is **nil**, then return Q.E.D.
 - Otherwise, return a pruned version of the failing path to the user for further analysis

[Our Approach - Elaborations]

- The function (`state-predp trm`) is essentially defined as:

```
(defun state-predp (trm)
  (and (not (intersectp-eq (all-fnnames trm) '(t+ hide)))
       (equal (all-vars trm) '(n))))
```

- Thus, the user can cause introduce an input predicate by introducing a **hide**
- We chose to define our own term rewriter because simplicity is more important than efficiency
 - The rewriter does extract rewrite rules from the current ACL2 world
- Our “model checker” is an compiled, optimized (to an extent), explicit-state, breadth-first search through the predicate state graph
- The prover also supports assume-guarantee reasoning through the use of **forced** hypothesis

[Mutual Exclusion Continued]

- Beginning with `(ok n)`, the prover generates the following set of predicates:

```
(ok n)
(equal (status (a) n) ':critical)
(equal (status (b) n) ':critical)
(equal (status (a) n) ':try)
(equal (status (b) n) ':try)
(in-critical n)
(equal (critical-id n) (a))
(equal (critical-id n) (b))
```

- The resulting graph has 20 nodes and verifies that `(ok n)` is never `nil`
- We can further reduce the graph to 6 nodes by hiding `:try` terms:

```
(defthm coerce-try-status-to-input
  (equal (equal (status p n) ':try)
    (hide (equal (status p n) ':try))))
```

[MESI cache example-1]

- More complex example: a high-level definition of the MESI cache coherence protocol

- Ok, technically we only model MESI cache states

- System defined by following state variables:

- (mem c n) – shared memory data for cache-line c

- (cache p c n) – data for cache-line c at proc. p

- (valid c n) and (excl c n) – sets of processor id.s which define the MESI cache states

- We will need a few constrained functions:

```
(encapsulate (((proc *) => *) ((op *) => *)
              ((addr *) => *) ((data *) => *))
  (local (defun proc (n) n)) (local (defun op (n) n))
  (local (defun addr (n) n)) (local (defun data (n) n)))

(encapsulate (((c-1 *) => *)) (local (defun c-1 (a) a)))
```

```

(define-system mesi-cache
  (mem (c n) nil
    (cond ((/= (c-1 (addr n)) c) (mem c n-))
      ((and (= (op n) :flush)
        (in1 (proc n) (excl c n-)))
        (cache (proc n) c n-))
      (t (mem c n-))))

(cache (p c n) nil
  (cond ((/= (c-1 (addr n)) c) (cache p c n-))
    ((/= (proc n) p) (cache p c n-))
    ((or (and (= (op n) :fill) (not (excl c n-)))
      (and (= (op n) :fille) (not (valid c n-))))
      (mem c n-))
    ((and (= (op n) :store) (in1 p (excl c n-)))
      (s (addr n) (data n) (cache p c n-)))
    (t (cache p c n-))))

(excl (c n) nil
  (cond ((/= (c-1 (addr n)) c) (excl c n-))
    ((and (= (op n) :flush)
      (implies (excl c n-)
        (in1 (proc n) (excl c n-))))
      (sdrop (proc n) (excl c n-)))
    ((and (= (op n) :fille) (not (valid c n-)))
      (sadd (proc n) (excl c n-)))
    (t (excl c n-))))

(valid (c n) nil
  (cond ((/= (c-1 (addr n)) c) (valid c n-))
    ((and (= (op n) :flush)
      (implies (excl c n-)
        (in1 (proc n) (excl c n-))))
      (sdrop (proc n) (valid c n-)))
    ((or (and (= (op n) :fill) (not (excl c n-)))
      (and (= (op n) :fille) (not (valid c n-))))
      (sadd (proc n) (valid c n-)))
    (t (valid c n-))))

```

[MESI cache example-3]

- Property: the value read by a processor is the last value stored.
- A codification in ACL2 of this property as the target invariant (`ok n`):

```
(encapsulate (((p) => *) ((a) => *))  
  (local (defun p () t)) (local (defun a () t)))
```

```
(define-system mesi-specification  
  (a-dat (n) nil  
    (if (and (= (addr n) (a))  
              (= (op n) :store)  
              (in1 (proc n) (excl (c-1 (a)) n-)))  
      (list (data n))  
      (a-dat n-)))
```

```
(ok (n) t  
  (if (and (a-dat n-)  
            (= (proc n) (p))  
            (= (addr n) (a))  
            (= (op n) :load)  
            (in (p) (valid (c-1 (a)) n-)))  
      (= (g (a) (cache (p) (c-1 (a)) n-))  
         (car (a-dat n-)))  
      (ok n-))))
```

[MESI cache example-4]

- Key rewrite rule to introduce case splits on the exclusive set (`excl c n`):

```
(defthm in1-force-split
  (equal (in1 e s)
    (cond ((not s) nil)
          ((c1 s) (equal e (scar s)))
          (t (hide (in1 e s))))))
```

- Prover generates following predicate set and explores resulting graph (48 nodes):

```
(ok n)
(a-dat n)
(valid (c-1 (a)) n)
(in (p) (valid (c-1 (a)) n))
(excl (c-1 (a)) n)
(in (p) (excl (c-1 (a)) n))
(c1 (excl (c-1 (a)) n))
(equal (scar (excl (c-1 (a)) n)) (p))
(equal (g (a) (cache (scar (excl (c-1 (a)) n))
                    (c-1 (a)) n))
  (car (a-dat n)))
(equal (g (a) (cache (p) (c-1 (a)) n))
  (car (a-dat n)))
(equal (g (a) (mem (c-1 (a)) n))
  (car (a-dat n)))
```

[Conclusions and Future Work]

- Prover can be effective but requires thought:
 - Careful consideration of system definition and specification relative to existing operators and rewrite rules
 - Determination of which terms should be hidden and the possible addition of auxiliary variables
- Improvements to the Prover:
 - Interfaces to external model checkers for Phase 2
 - Compress/Reduce resulting predicate graph based on equality reasoning between state and input predicates
 - Various improvements to built-in “model checker”
- Many more example systems and effort to integrate with RTL definitions and existing library
- Need to develop more comprehensive compositional methodology
