

CS354P

DR SARAH ABRAHAM

OVERVIEW: GRAPHICS

WHAT IS GRAPHICS?

- ▶ Broad area that includes anything involved in the process of getting pictures onto a screen
 - ▶ Rendering pipeline
 - ▶ Physical simulation
 - ▶ Procedural generation
 - ▶ Animation
 - ▶ Geometry and modelings
 - ▶ etc...

WE'LL FOCUS ON THE RENDERING FEATURES

- ▶ This will be as high-level as possible, since we won't have time to cover the actual math/hardware in any detail
- ▶ We'll come back to some of these features when we talk more about the GPU pipeline

GRAPHICS PIPELINE OVERVIEW

- ▶ CPU (Central Processing Unit) passes functionality and data to the GPU (Graphics Processing Unit)
- ▶ GPU architecture designed for *throughput*
 - ▶ High bandwidth, high latency
 - ▶ Goal is to process many similar operations in a parallel manner (i.e. efficiently apply mathematical operations to scene data)
- ▶ Considerations:
 - ▶ What data does the GPU need?
 - ▶ How do we get it to the GPU?
 - ▶ How do we specify what the GPU should do?

GRAPHICS LIBRARIES

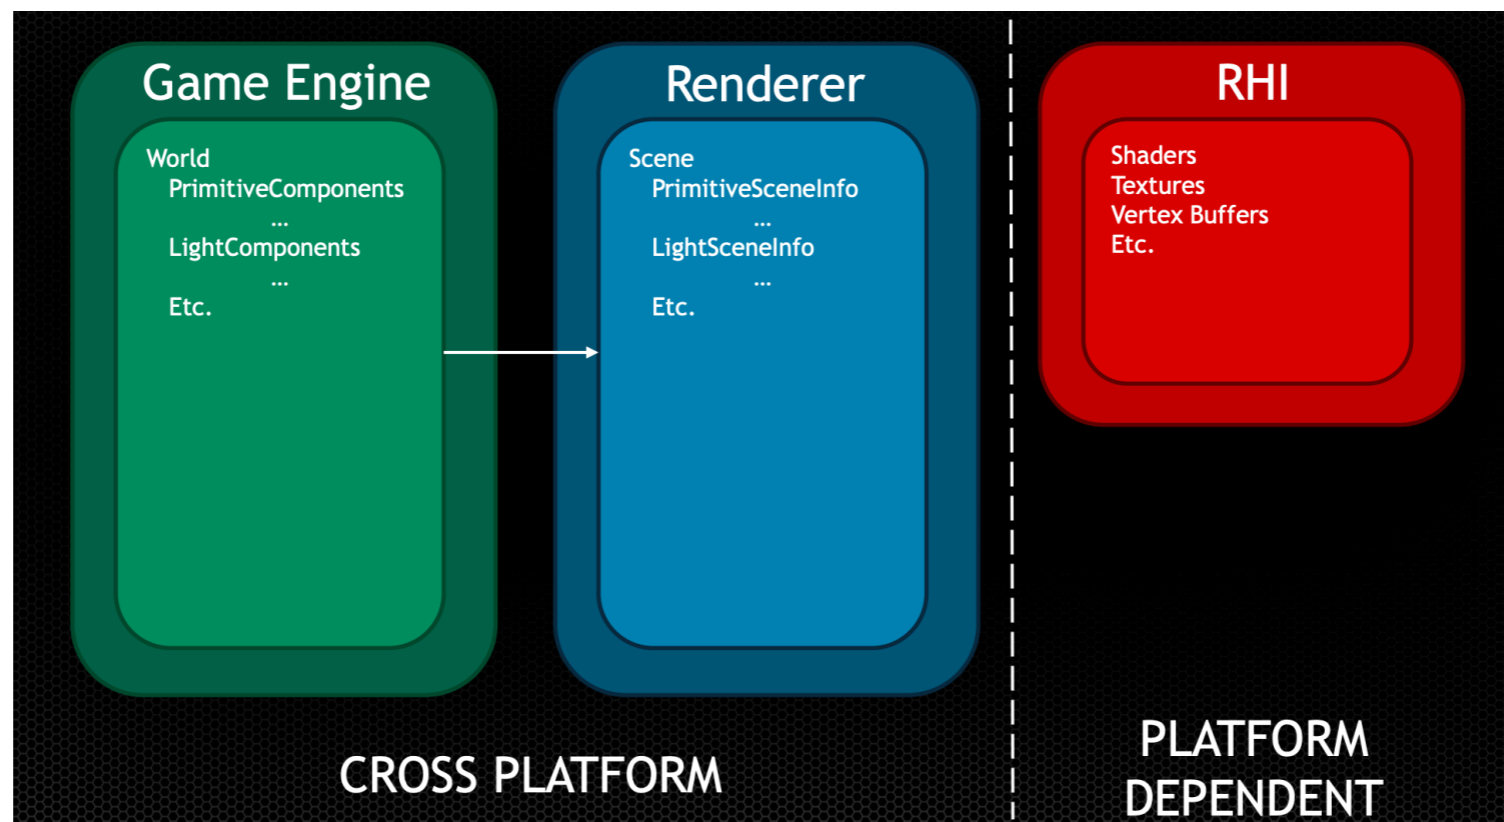

- ▶ Provide APIs for communicating data between the CPU and GPU
- ▶ OpenGL is a higher-level library created by the Khronos Group
 - ▶ Performs more of the setup and makes assumptions about memory to simplify developer interactions
 - ▶ OpenGL ES is graphics library for embedded systems such as mobile devices and web applications
- ▶ Vulkan is a lower-level library created by the Khronos Group
 - ▶ Allows greater flexibility and developer control by having developers perform setup and determine things like memory management/thread management
- ▶ DirectX is the family of libraries created by Microsoft
 - ▶ DirectX12 is equivalent to Vulkan in most functionality
- ▶ Metal is graphics library created by Apple and Sony has their own library as well...

HOW DOES THESE RELATE TO THE GRAPHICS HARDWARE?

- ▶ Graphics hardware has *API specifications* that these graphics libraries adhere to
 - ▶ Graphics libraries supported in hardware via drivers
- ▶ The choices that graphics libraries make effect their support by drivers:
 - ▶ OpenGL has tremendous backwards compatibility and support, and this complexity effects its performance
 - ▶ DirectX11 has similar issues but also more hand-optimized due to marketshare
 - ▶ DirectX12 and Vulkan are in the process of replacing OpenGL/DirectX11 in high-end games

UNREAL: SUPPORTING MULTIPLE HARDWARES

- ▶ Rendering Hardware Interface (RHI) is a C++ interface to allow communication from UE5's rendering code to platform-dependent implementations of graphics APIs
- ▶ Also use of an internal shader cross compiler (HLSLCC)

WHAT ARE SHADERS?

- ▶ Small programs that run on GPU hardware
- ▶ GPUs have **programmable** pipelines which allow these compiled programs to be linked to pipeline stages and dictate how data passed from the CPU is processed
 - ▶ Apply transforms to vertex data
 - ▶ Use texture information
 - ▶ Apply post-processing effects
 - ▶ etc...
- ▶ Final output is an image buffer with each pixel “shaded” accordingly

AT LAST...THE PRETTY STUFF...

- ▶ Shaders are where we specify things like lighting models, texture mapping, material interactions and more
 - ▶ i.e. they make things pretty

Guilty Gear Strive

MATERIALS AND PHYSICALLY-BASED RENDERING (PBR)

- ▶ Concept of the visual qualities a mesh object has
 - ▶ Textures are part of this but called **materials** because they represent the actual material properties in relation to the **lighting equation**
- ▶ Take incoming light data and apply it to the physically-based lighting function of the material to determine the final pixel color output

BRDFs

- ▶ Bidirectional reflectance distribution function
- ▶ Defines how a material reflects light based on the angle of observation
- ▶ Determines ratio of reflected radiance
 - ▶ Physically-based
 - ▶ Empirically studied by material sample

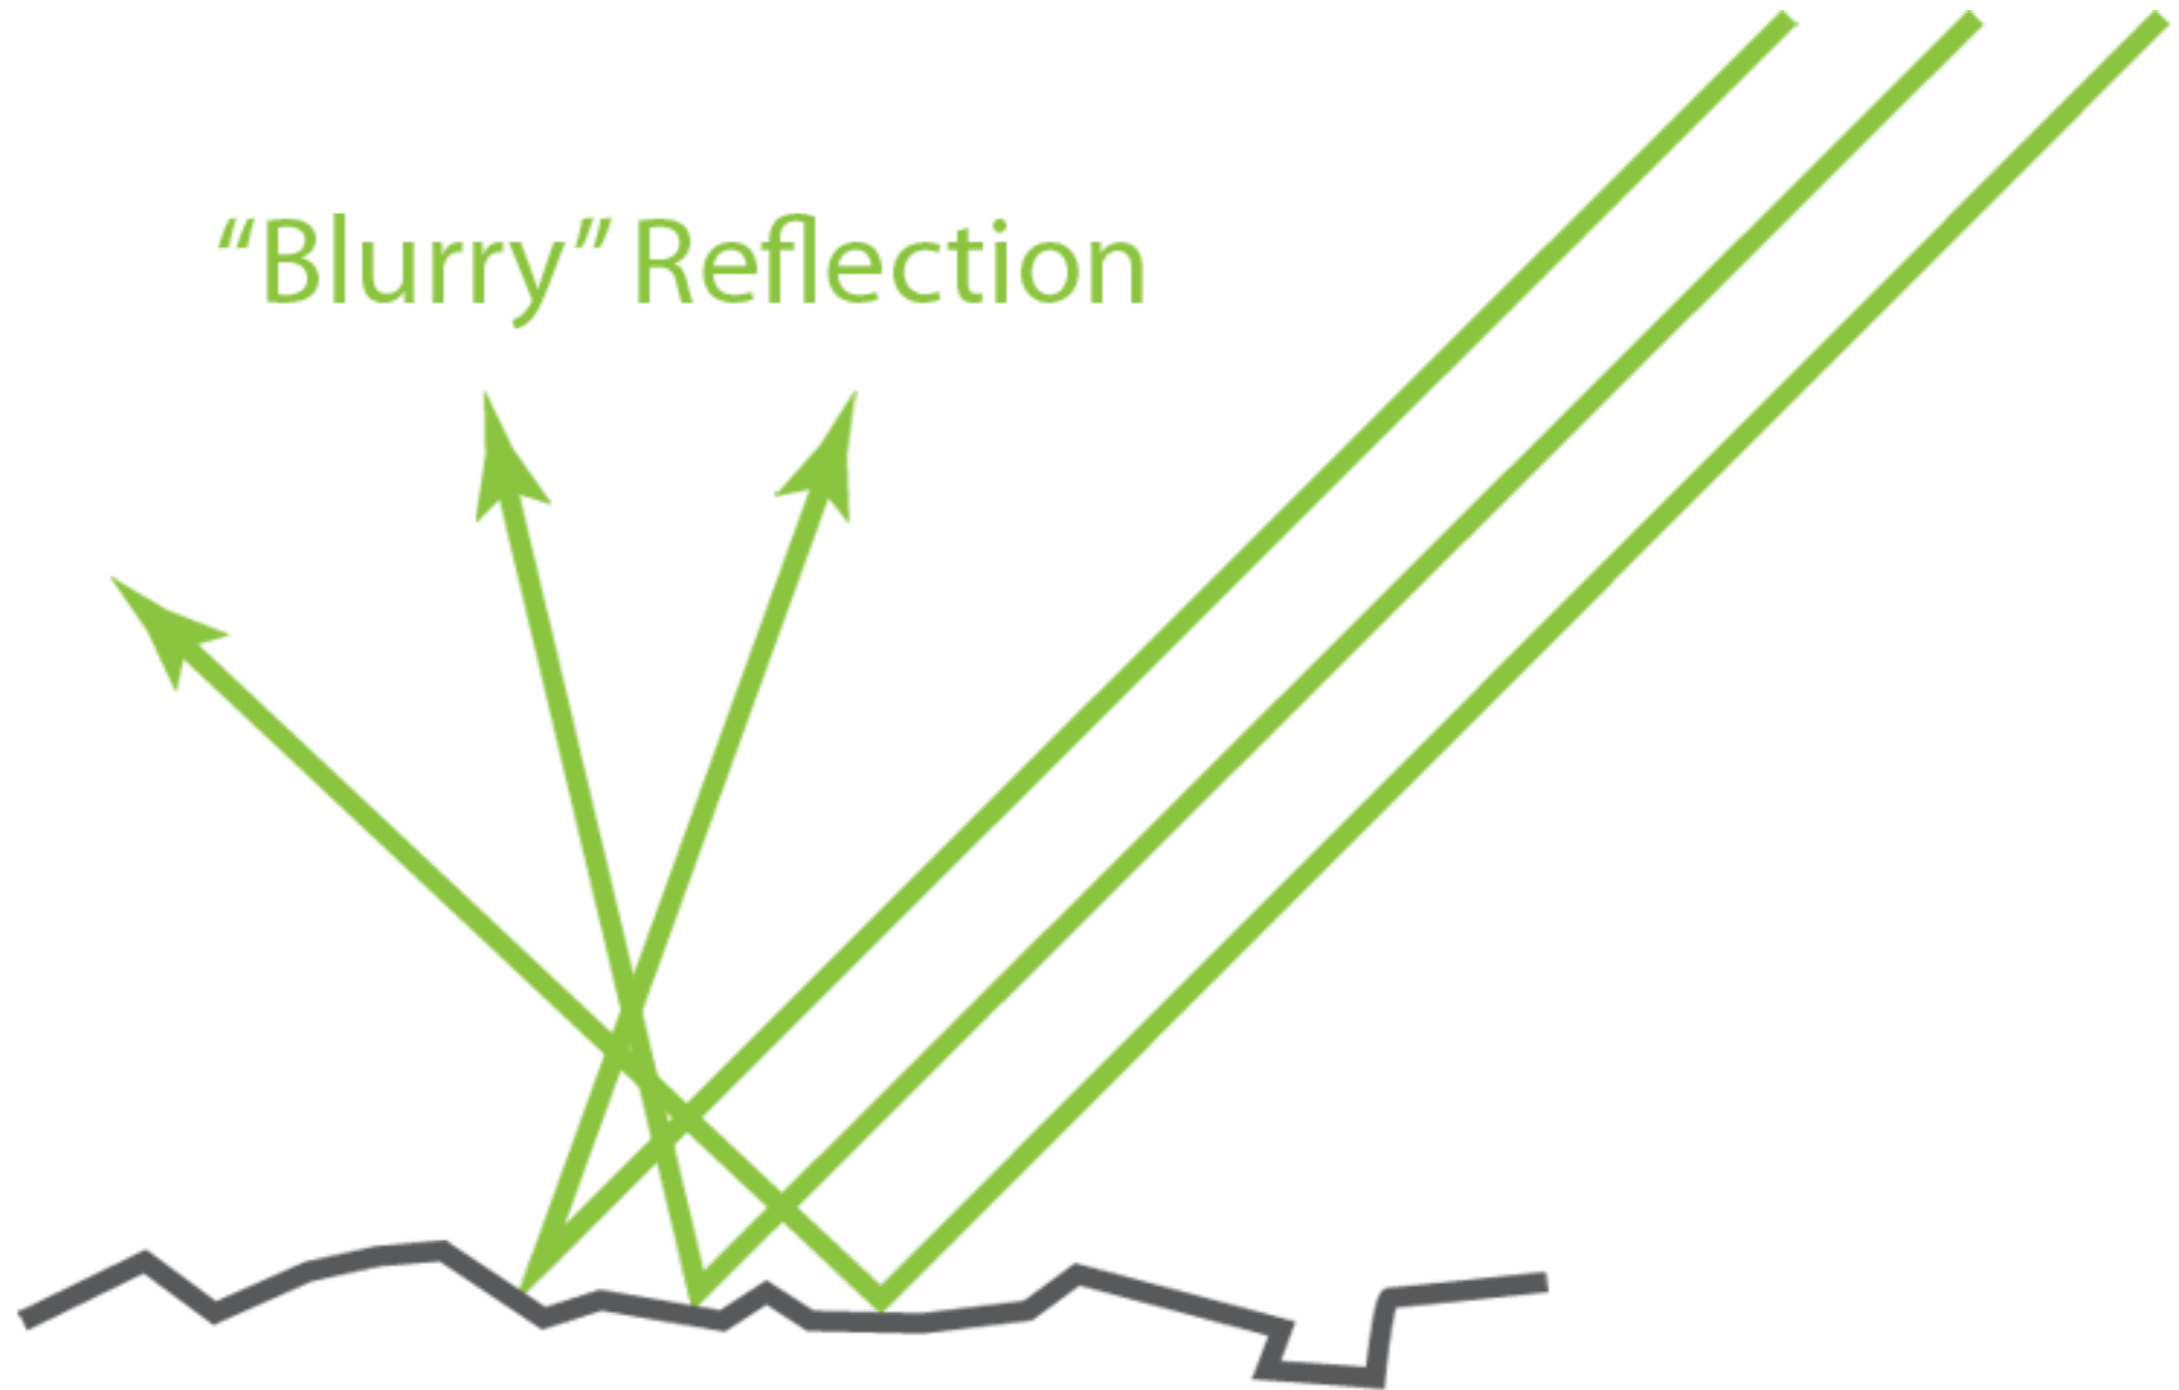

MATERIAL PARAMETERIZATION

- ▶ Base Color (Albedo)
 - ▶ Diffuse color based on scattering/absorption of light wavelengths
- ▶ Roughness
 - ▶ Amount of microsurfaces and imperfections on material's surface leading to light scatter
- ▶ Metallic
 - ▶ Degree of "metalness" including colored reflections and any diffusion from corrosion/dirt on surface
- ▶ Reflectance
 - ▶ Amount of reflected light on non-metallic surfaces

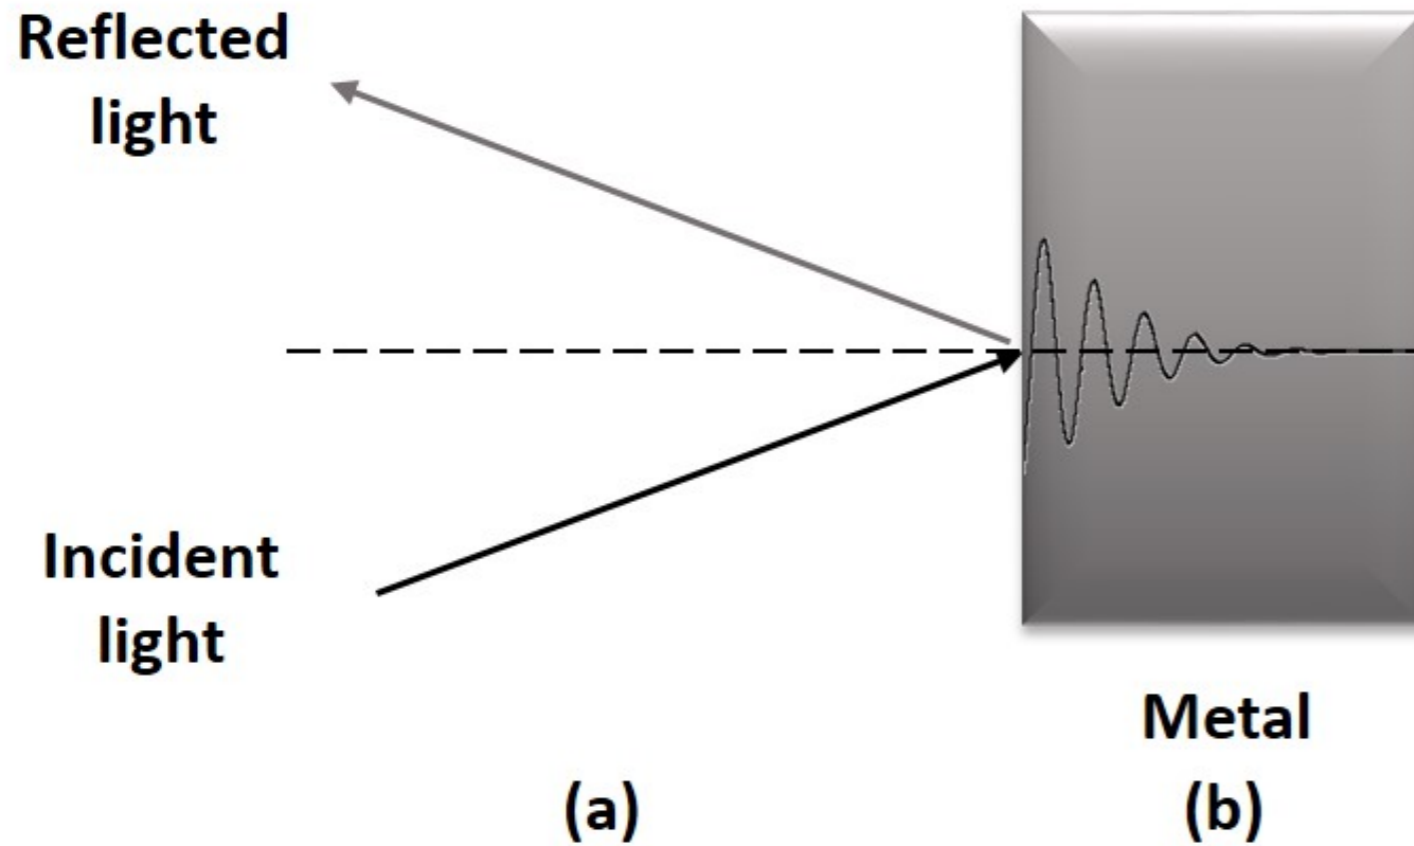

ALBEDO

ROUGHNESS

METALLIC

REFLECTANCE

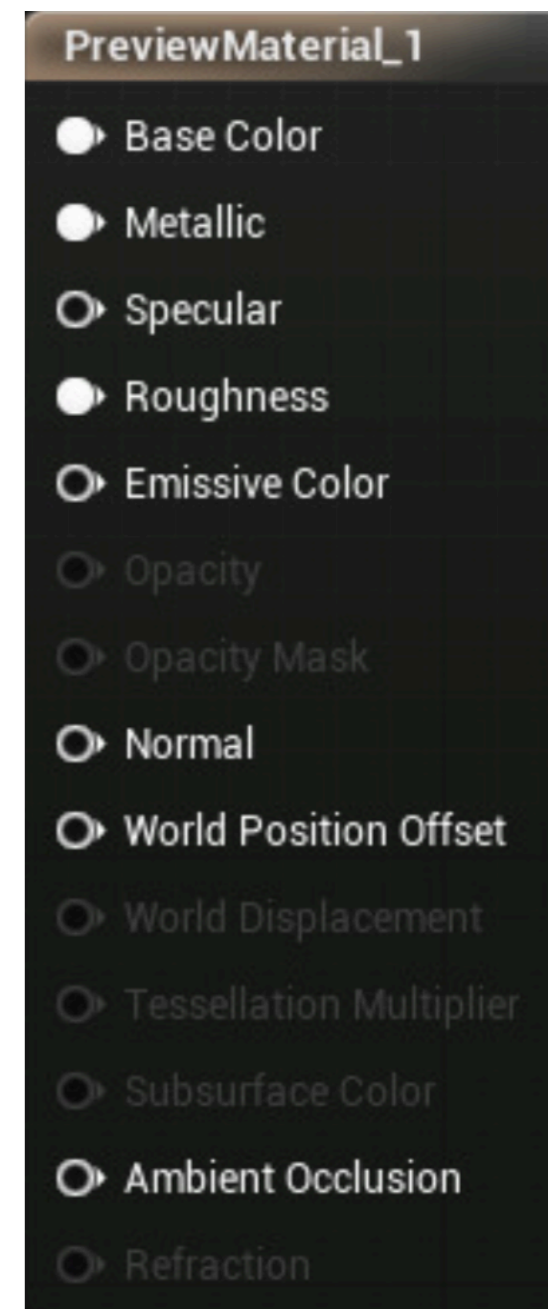

MATERIALS IN UNREAL

- ▶ Assets that can be applied to meshes to control the mesh's lighting properties
- ▶ Uses a node-based scripting language that connects to the underlying shader programming language (in this case, HLSL)
 - ▶ Allows artists to create visual effects without any shader programming knowledge
 - ▶ Possible to access HLSL directly but not required in many cases

MATERIAL PROPERTIES AND INPUTS

- ▶ Material properties specify things like blend mode, shading model, level of detail, translucency, and shader pipeline optimizations among others
- ▶ Material inputs specify the material parameterization discussed earlier
 - ▶ Can connect to art programs like Substance, which specialize in generating procedural, PBR-based textures and materials

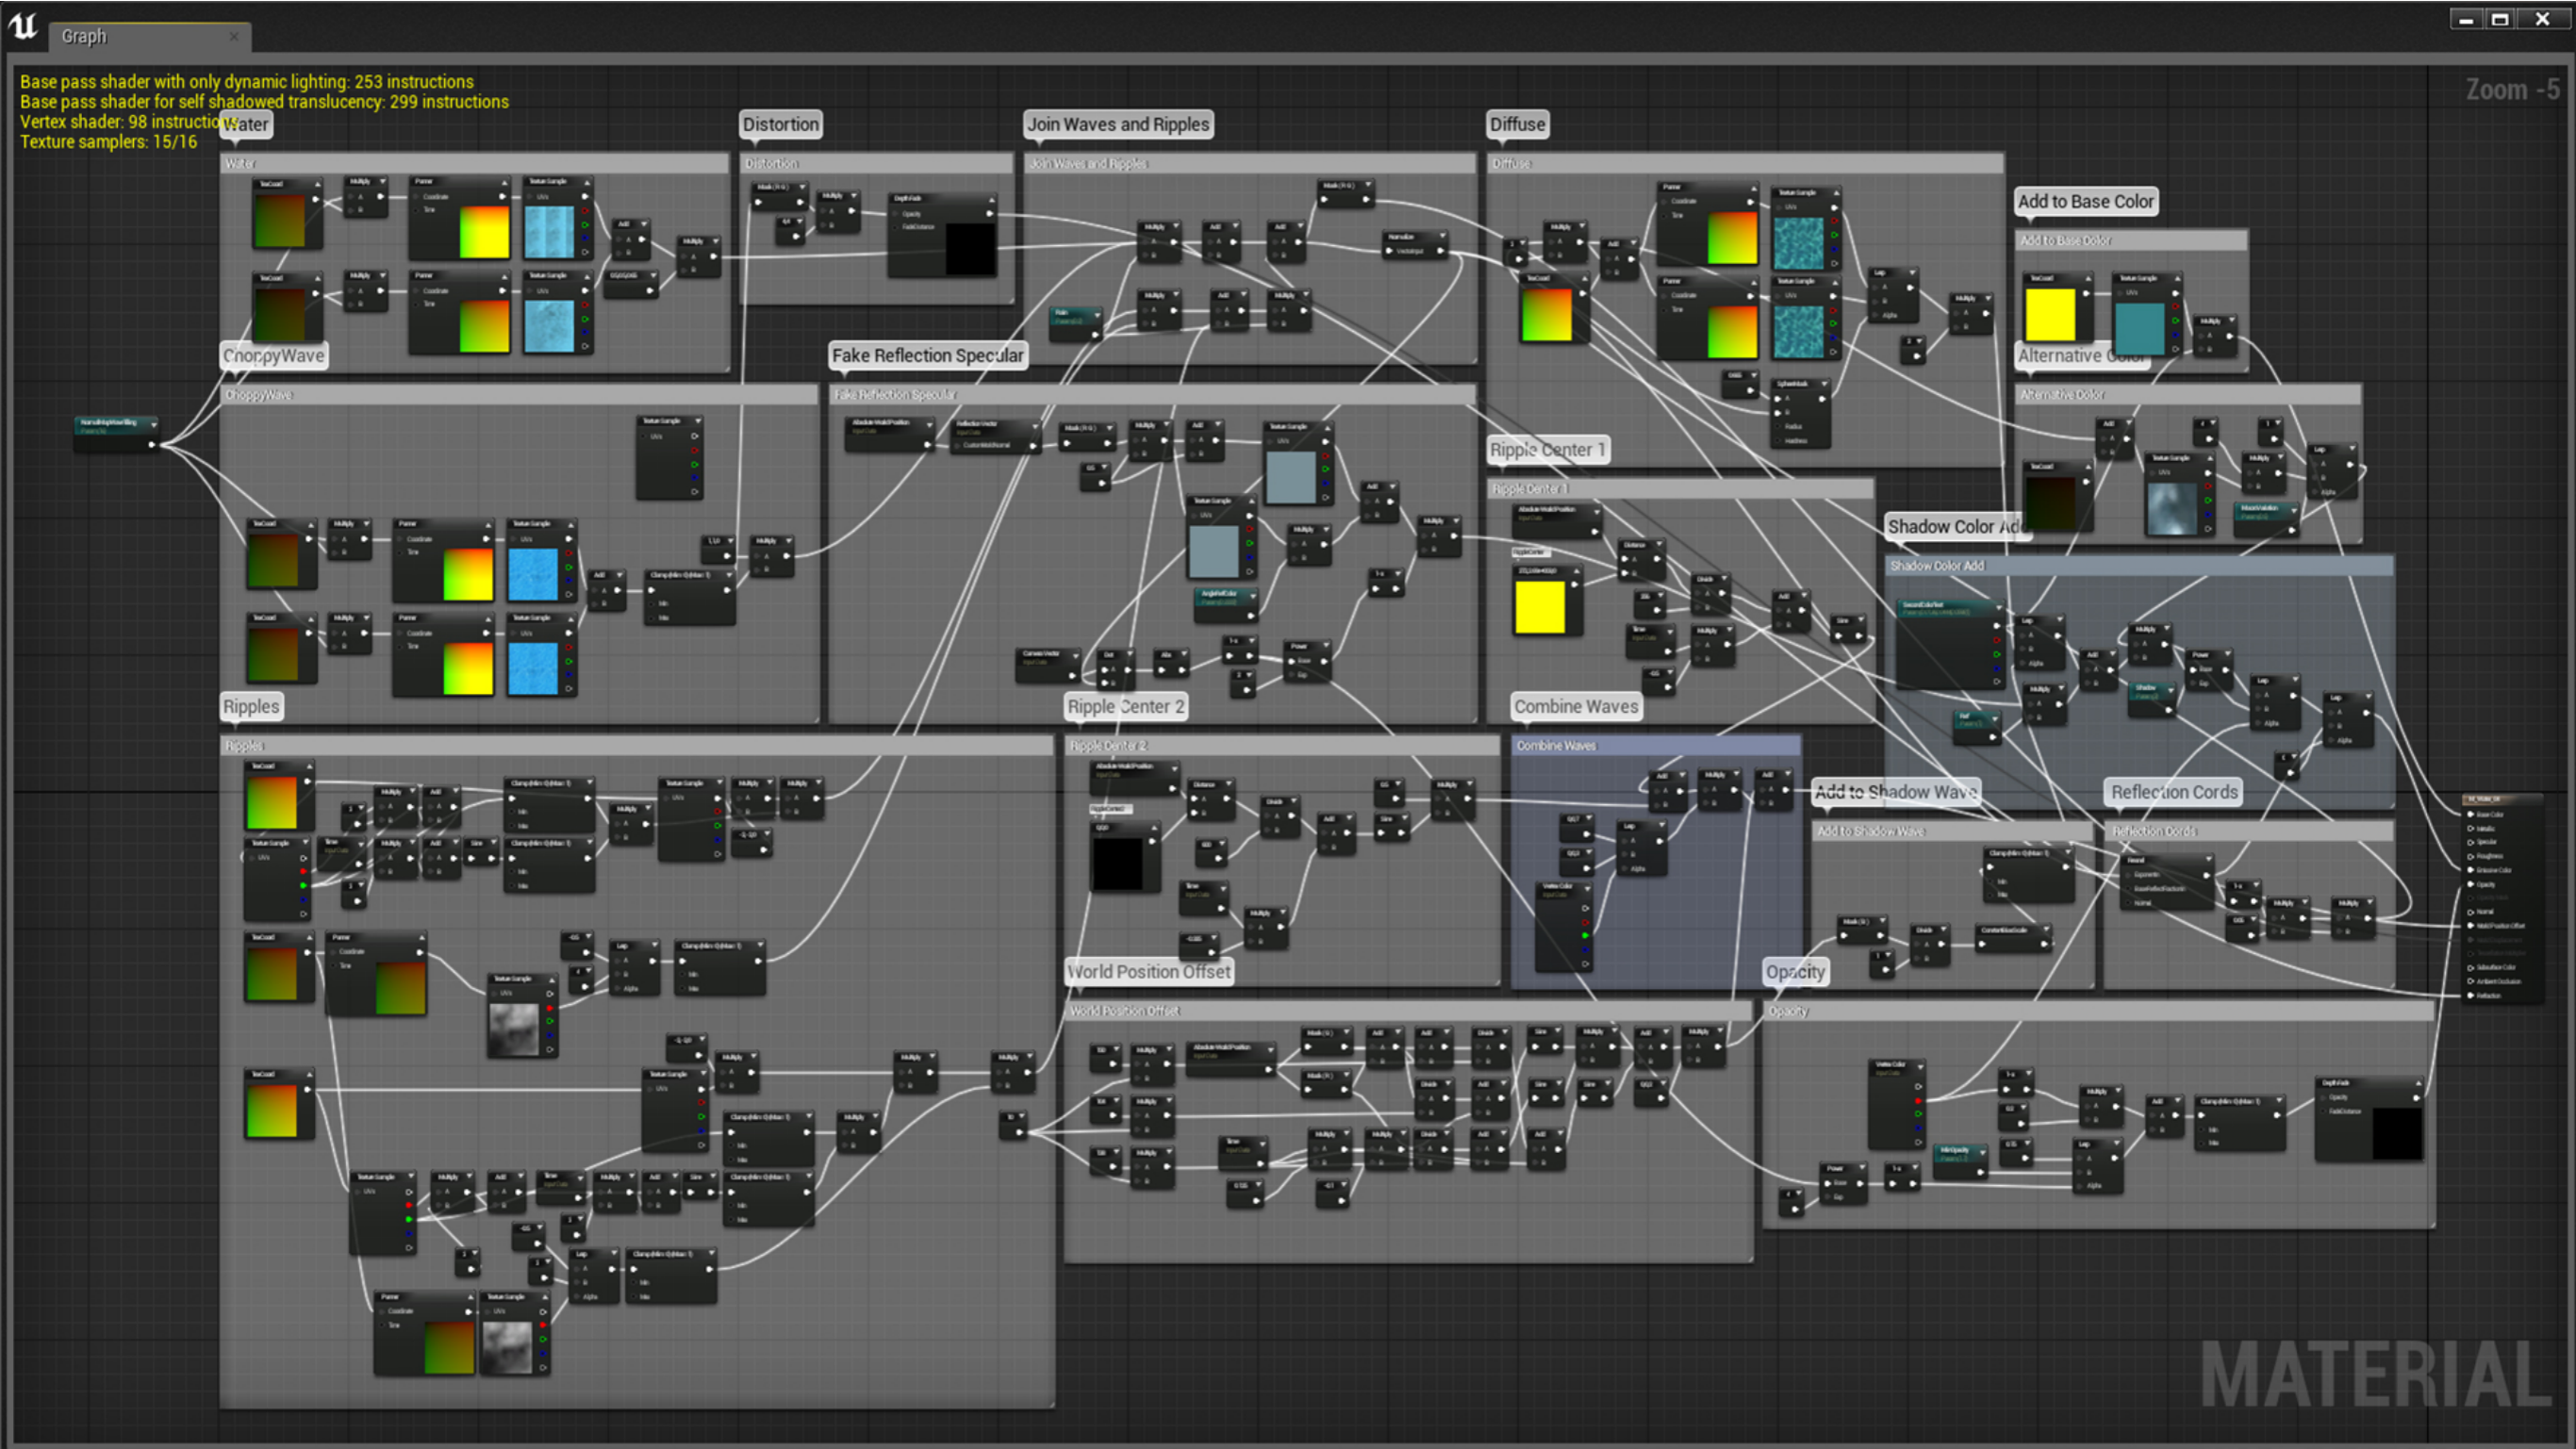

Material Inputs

PUTTING IT ALL TOGETHER...

- ▶ Can create very simple to very complex effects...

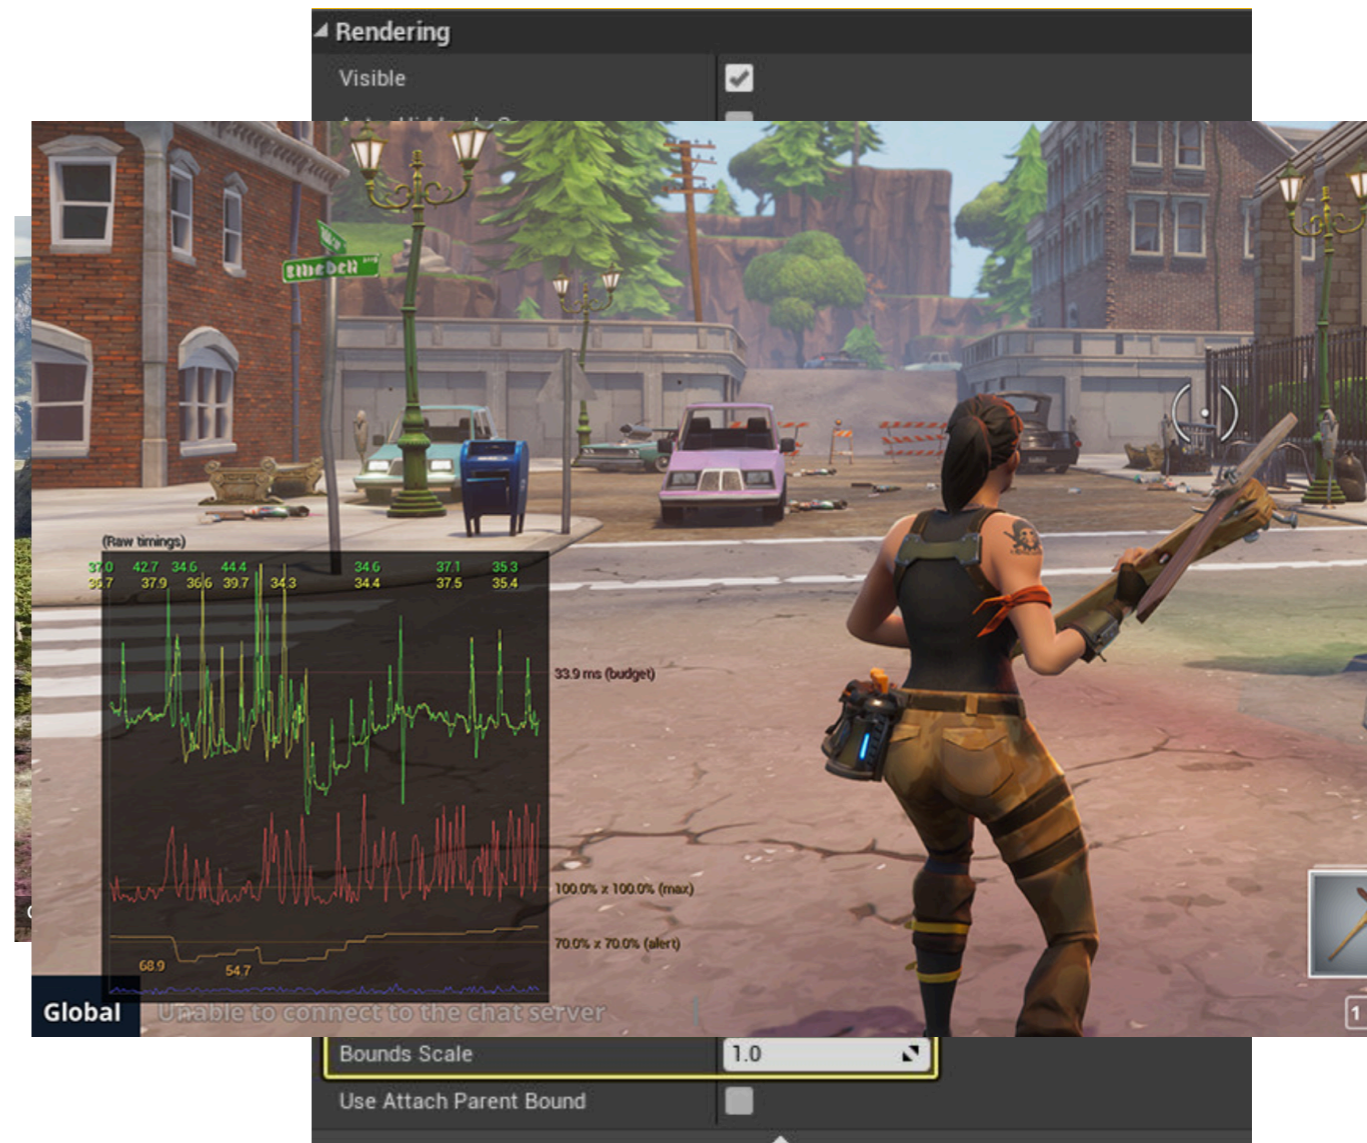

<https://forums.unrealengine.com/community/work-in-progress/7372-water-material>

BUILT-IN EFFECTS

- ▶ Unreal has a ton of beautiful effects/features you can use “out of the box”
- ▶ Sky Atmospheres create physically-based sky and atmospheric rendering with time of day
- ▶ Multiple types of visibility culling plus per-instance settings
- ▶ Many, many pre-baked and dynamic lighting setups
- ▶ Dynamic resolution support for adjusting resolution per frame

POST-PROCESSING EFFECTS

- ▶ Effects done at the end of the shading pipeline to apply visual changes globally to the scene
 - ▶ Unreal uses Post-Process Volumes that apply effect within that volume
- ▶ Effects include:
 - ▶ Anti-aliasing
 - ▶ Bloom
 - ▶ Depth of Field
 - ▶ Lens Flare
 - ▶ Chromatic Aberration
 - ▶ Vignette

POST PROCESS MATERIALS

- ▶ Can also apply Post Process Materials, which are shaders that work in the scene's texture space*

Some post-process material examples

* Note to students who have taken graphics: I'm differentiating texture and screen space because Unreal assumes a **deferred shading pipeline** (which we'll touch on later) but you can think of this as a fragment shader

PARTICLE SYSTEMS

- ▶ Rules and memory management for a large body of point masses to create visual effects
 - ▶ Creation of fluid effects
 - ▶ Creation of crowd behaviors/flocking
 - ▶ etc..
- ▶ UE5 has two particle systems:
 - ▶ Cascade is older, better documented system with less flexibility
 - ▶ Niagara is newer, less documented system with greater flexibility
- ▶ Cascade and Niagara both designed for designer/artist use
 - ▶ Niagara is more “next-gen” allowing designers/artists to create more lower-level functionality with programmer assistance

PARTICLE EFFECTS IN ACTION

RAY TRACING

- ▶ Technique that emulates the physical equations of **light transport** to get an accurate representation of light-material interaction
- ▶ Increasingly common in modern systems with growing hardware support
- ▶ Unreal supports two kinds of ray tracing
 - ▶ Path tracing (offline, expensive form of raytracing to correctly emulate light transport)
 - ▶ Hybrid ray tracing (real-time form of raytracing that is used in tandem with "raster" style effects)

HYBRID RAYTRACING EXAMPLE: ARCHITECTURE STUDIOS
